Not illustrated. 1885 Excerpt: . . . proper size of the beam can be determined by finding the maximum bending moment and proportioning the beam accordingly. Equilibrium is obtained when the bending moment is equal to the moment of resistance. That is, when the external force multiplied by the leverage with which it acts is equal to the strength of the material in the cross section of the beam multiplied by the leverage with which it acts. The ultimate moment of resistance for a wrought-iron beam of symmetrical form is  $42000 \frac{M}{d}$   $84000 \frac{M}{d}$  depth  $d$  depth of beam in the direction in which the force acts.  $I$  the moment of inertia about the axis at right angles to the direction of the force. The greatest safe moment of resistance as adopted in our tables is one-third ( $i$ ) of above,  $28000 \frac{M}{d}$   $28000 \frac{M}{d}$  The co-efficient to be changed according to the factor of safety desired. The rule would thus be  $le. n$ --Co-efficient  $d$  RULE FOR BEAMS BEARING IRREGULAR LOADS. Find by the methods described in preceding article the maximum bending moment in inch-lbs. for the loads. Divide the moment by the proper co-efficient as described above. Find in the tables, pages 92-96, a beam whose inertia divided by its depth is not less than this quotient; which will be the beam required. In some instances the maximum bending moment can be most readily found by the use of diagrams, as described in the succeeding article. When this is done use...
